

AI Product Search - V7-20260815 Customer Release Notes

V7-20260815 is a **cumulative release**. Deploy the Function App package and the X++ package from this release only.

Included packages

- CCAISearch-Deploy-v1.0.zip - Azure Function App deployment package
- FTA_CCAISearch_V7_20260815.axpp - Dynamics 365 Finance and Operations model package

Download both files from the [V7-20260815 GitHub release](#).

Function App changes

The Function App now accesses the destination Storage account through its **system-assigned managed identity** and `DefaultAzureCredential` instead of a storage connection string.

Security behavior

- D365 reads the storage connection string from **Key Vault**.
- D365 extracts only the blob endpoint URL, for example `https://<account>.blob.core.windows.net`.
- Only that non-secret endpoint is sent to the Function App.
- The storage account key never leaves D365 and is not included in request bodies, logs, or telemetry.
- The full connection string remains in Key Vault for the Azure AI Search data source.
- No storage secret is stored in the Function App configuration.

Required Azure setup

After deploying the Function App:

- 1 Open the Function App in the Azure portal.
- 2 Select **Identity**.
- 3 Enable **System assigned** managed identity and save.
- 4 Open the destination Storage account.
- 5 Select **Access control (IAM)**.
- 6 Assign **Storage Blob Data Contributor** to the Function App managed identity.

The role assignment requires **Owner** or **User Access Administrator** permissions on the Storage account. Without this role assignment, product data cannot be written to the destination container. No additional storage app setting is required.

Additional Function App fixes

- Corrected CLR exception handling in `exportInitialProductData` and `copyData`.
- Aligned DMF refresh type with sync mode: **FullPush** for initial export and **IncrementalPush** thereafter.
- Added error logging for DMF refresh and copy operations.

Customer extension points

The X++ package supports customer-specific changes in a separate extension model. Do not modify the FTA model directly.

Custom Azure AI Search index schema

Create a new JSON resource in the customer model by copying the standard index schema resource. Then override the resource name through Chain of Command (CoC):

```
[ExtensionOf(classStr(CCAISearchProductSearchHelper))]  
final class CustomerSearchProductSearchHelper_Extension  
{  
    protected SysElementName getIndexSchemaResourceName()  
    {  
        next getIndexSchemaResourceName();  
  
        return resourceStr(CustomerProductSearchIndexSchema);  
    }  
}
```

Keep the required standard fields and keep %1 in the JSON name value. The application replaces %1 with the generated index name.

Additional search-result fields

To populate an additional field from the Azure AI Search response, extend the result-mapping method:

```
using Newtonsoft.Json.Linq;  
  
[ExtensionOf(classStr(CCProductSearchProcessData))]  
final class CustomerProductSearchProcessData_Extension  
{  
    protected void mapSearchResult(  
        JObject _searchResult,  
        InventTable _inventTable,  
        EcoResCategoryHierarchy _hierarchy,  
        CCProductSearchTmpTable _itemTable)  
    {  
        next mapSearchResult(  
            _searchResult,  
            _inventTable,  
            _hierarchy,  
            _itemTable);  
  
        _itemTable.CustomerField =  
            _searchResult.GetValue('CUSTOMERFIELD').ToString();  
    }  
}
```

The corresponding field must exist in CCProductSearchTmpTable or in a customer table extension. The response is processed once; the customer does not need to parse the complete JSON array again.

Deployment order

- 1 Deploy CCAISearch-Deploy-v1.0.zip.
- 2 Enable managed identity and assign **Storage Blob Data Contributor**.
- 3 Import FTA_CCAISearch_V7_20260815.axpp into D365 F&O.
- 4 Add customer CoC extensions only if required.
- 5 Complete the F&O configuration and initialize the search index.

See the deployment guides:
